Fig. S1 XRD patterns of NiLa-X@CC and Ni LDH@CC precursors.

Note that when the molar ratio of the Ni/La source ranged from 0 to 1, the only presented phase of all the samples was $La(OH)_3$ (PDF #13-0084), indicating the precursors were $Ni_xLa_{1-x}(OH)_3$. Moreover, after increasing the ratio of Ni and La to 2 (NiLa-2), the only phase which can be identified was a typical LDH phase (PDF #30-1835) [S1, S2], thus the associated compounds were considered as NiLa LDH. When the Ni content was continuously increased without any addition of La source, a pure Ni LDH phase can be observed in the sample of Ni LDH@CC.

Fig. S2 Schematic diagram of transient photo-induced voltage setup and its working mechanism.

The TPV test system is used to characterize and analyze the kinetic processes of photoelectron extraction and interfacial charge transport in materials, which is schematically demonstrated in this figure. A laser pulse, whose wavelength is 355 nm and pulse width is 5 ns, generated from the third harmonic Nd: YAG laser instrument is applied to the surface of the powder samples supported on a platinum mesh substrate, inducing the separation and transfer of photogenerated charges within those samples. The resulting potential difference on the sample surface is detected by the connected platinum mesh and oscilloscope. Subsequently, the potential change is captured by the information acquisition card to obtain the corresponding transient photovoltage signal. Herein, the change of photo-induced voltage is recorded at a more precise time span, which can more deeply analyze the properties and mechanism of the material.

Ni$_3$S$_2$@CC in 1 M KOH electrolyte at a catalytically active potential of 1.41 V *vs*. RHE

in 1 M KOH with an inset of the equivalent circuit.
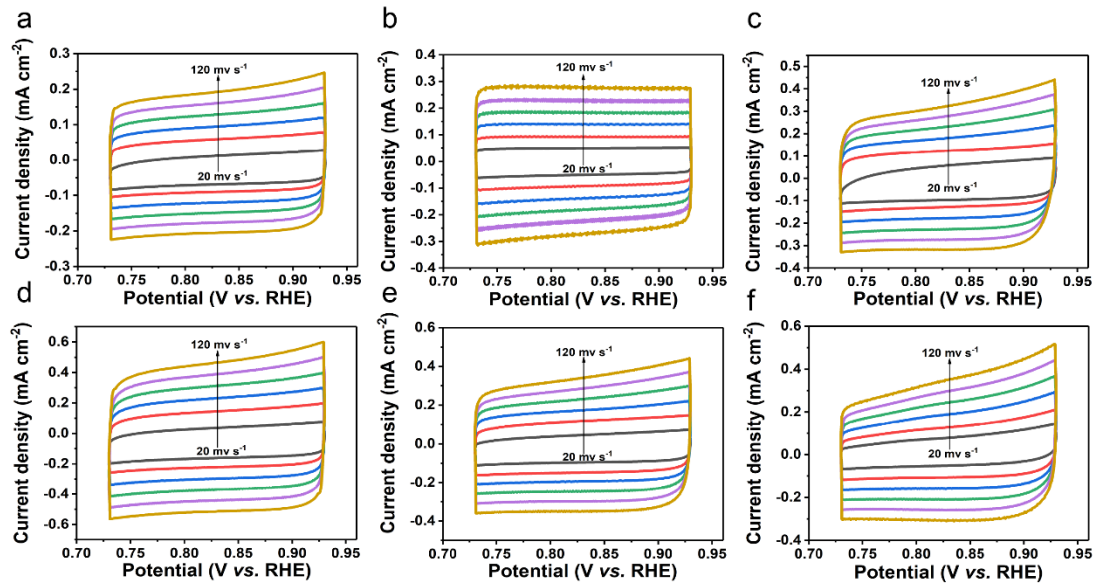

Fig. S13 Corresponding CV curves withinthe   non-Faradic region of **a** NLOS-0@CC,
b NLOS-0.25@CC, **c** NLOS-0.5@CC, **d** NLOS-1@CC, **e** NLOS-2@CC, and **f**
Ni$_3$S$_2$@CC recorded at the scan rates of 20, 40, 60, 80,100, and 120 mV s^{-1}, respectively.
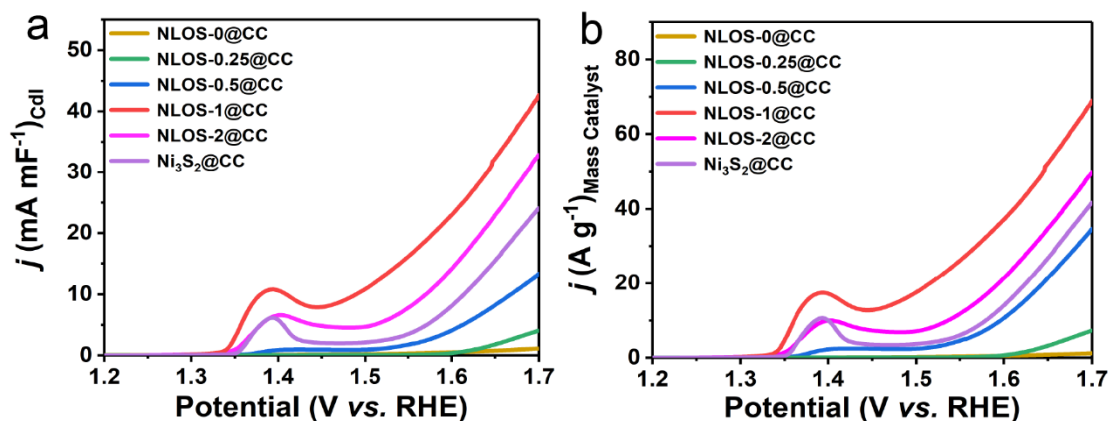

Fig. S14 IR-corrected LSV curves normalized against the **a** C_{dl} value, and **b** loading mass of NLOS-0@CC, NLOS-0.25@CC, NLOS-0.5@CC, NLOS-1@CC, NLOS-2@CC, and Ni_3S_2@CC. Note that the electrochemical active surface area (ECSA) value is linearly proportional to C_{dl} (ECSA=C_{dl}/C_s), and the C_s is assumed to be identical for all probed samples in our case. Therefore, we directly normalized our current density to C_{dl} values to compare the intrinsic activity of our catalysts [S3, S4].
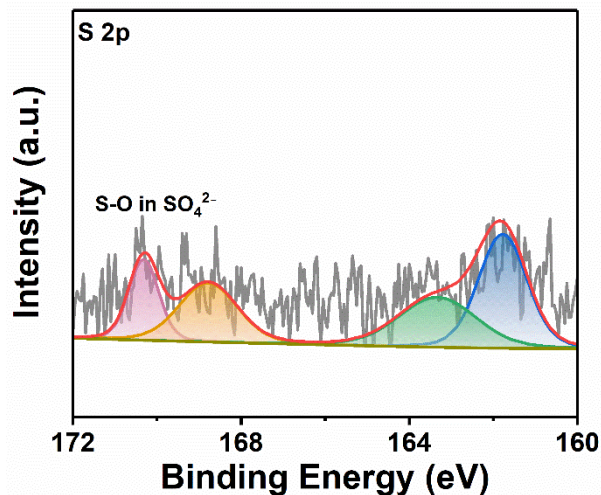

Fig. S15 High-resolution S 2p XPS spectrum of the post-OER NLOS-1@CC.

When compared with the high-resolution S 2p XPS spectrum in Fig. 2f, it can be easily found the concentration ratio between S-O species and M-S within lattice/surface S non-bonded to O increased from 1.79 of the pre-OER NLOS-1@CC to 2.49 of the post-OER one. The presence of S-O in the former case would arise from the surface passivation when exposing the sample to the air, and the increment of S-O species for the same sample after OER could be caused by the presence of the additionally SO_4^{2-}, which was *in-situ* formed and adsorbed on the surface during OER process.
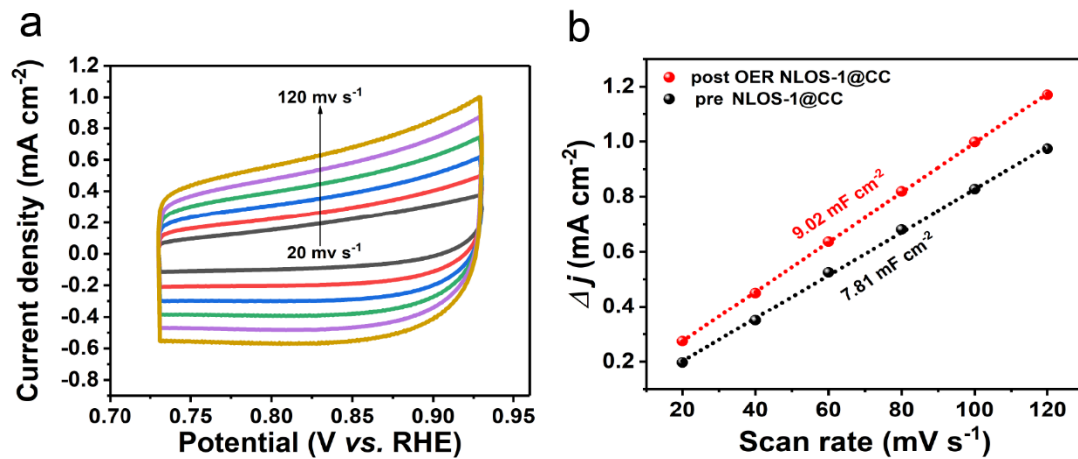

Fig. S16 a Corresponding CV curves within the non-Faradic region of the post-OER NLOS-1@CC; **b** C_{dl} of pre-OER NLOS-1@CC and post-OER NLOS-1@CC.
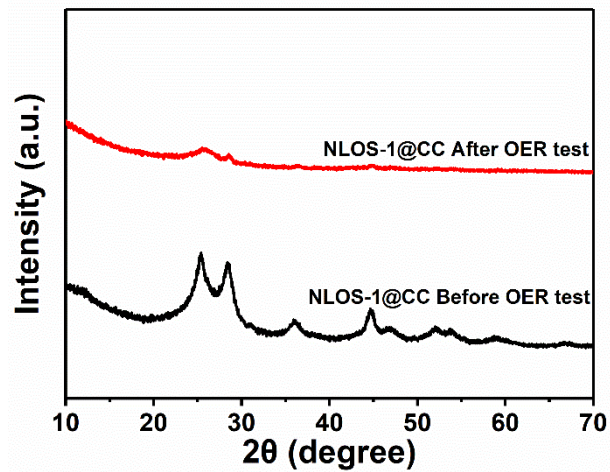

Fig. S17 XRD patterns of the pre- and post-OER NLOS-1@CC. Compared with that of the one before OER, the XRD data of post-OER NLOS-1@CC illustrates a significantly low-crystallinity La_2O_2S phase, indicating the occurrence of deep phase reconstruction during alkaline OER.
Fig. S18 The magnified HRTEM image of the post-OER NLOS-1, where NiOOH nanocrystals were alternatively separated by La(OH)$_3$ nanocrystals.
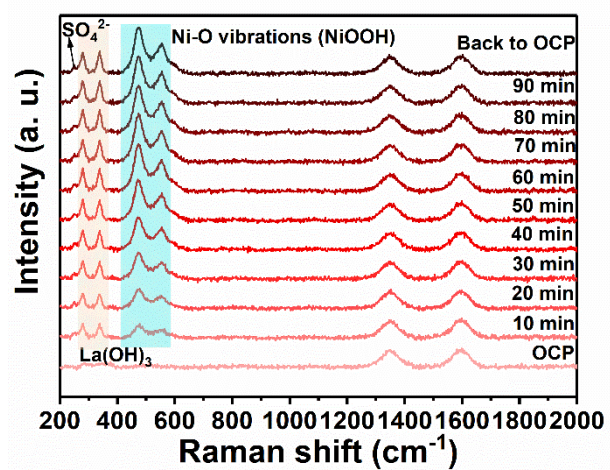

Fig. S19 Time-dependent *in-situ* Raman spectra of NLOS@CC at a fixed potential of 1.7 V *vs.* RHE.
Fig. S20 SEM–EDX and mapping images of the graphite rod before and after OER.
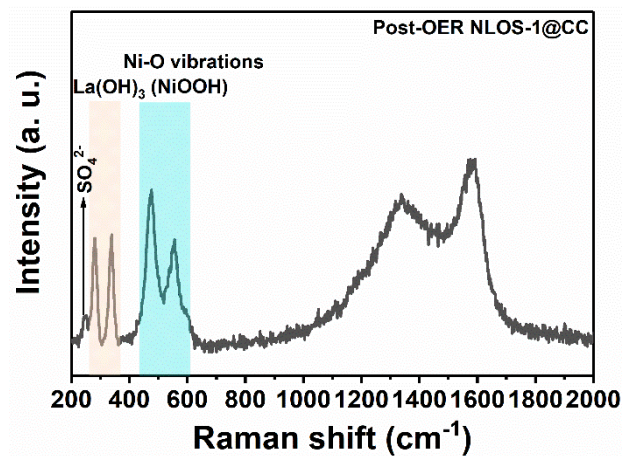

Fig. S21 Raman spectrum of the post-OER NLOS-1.

[a]This overpotential was obtained from the negatively-scanned LSV curve.

Table S3 EIS calculation parameters of NLOS-1@CC and reference samples at a catalytically active potential of 1.41V *vs.* RHE in 1 M KOH.

Samples	R_s	R_{ct}	CPE1-T	CPE2-P
NLOS-0@CC	1.7	1204	0.0012343	0.91912
NLOS-0.25@CC	1.6	378.8	0.0021428	0.88993
NLOS-0.5@CC	1.9	25.7	0.044625	0.80676
NLOS-1@CC	1.6	11.1	0.10022	0.77765
NLOS-2@CC	1.4	25.2	0.044316	0.80979
Ni_3S_2@CC	1.4	53.1	0.022986	0.85576

Table S4 The atomic ratio of La, Ni, S, and Fe for pre- and post-OER NLOS-1 obtained from TEM-EDS presented in Fig. 3 and Fig. 5 of the main text, respectively.

Atomic Ratio	La	Ni	S	Fe
Theoretic ratio	1	1	0.5	/
EDS (pre-OER)	1	1	0.49	/
EDS (post-OER)	0.93	1	0.12	0.006

Note after OER CP, there were still a certain amount of S atoms were preserved, which was supposed to contain the ones from the residual NLOS precatalyst, as well as the transformed oxyanions (SO_4^{2-}) adsorbed on the catalyst surface [S37]. Moreover, very few impurity Fe atoms from KOH electrolyte were doped into the reconstructed species, indicating the active structure which was responsible for the excellent OER was Fe-free $NiOOH/La(OH)_3$.

Table S5 The content of La, Ni and S in 1 M KOH electrolyte before and after 72 h OER CP tests of NLOS-1@CC and Ni_3S_2@CC.

Electrolyte	La (mg L^{-1})	Ni (mg L^{-1})	S (mg L^{-1})
Fresh	0.1	0.20	1.1
NLOS-1@CC after OER CP	0.1	0.20	1.8
Ni_3S_2@CC after OER CP	/	0.37	2.2

After 72 h OER CP at 100 mA cm^{-2}, the contents of La and Ni in the reaction electrolyte were almost the same, while much more S content can be found in the post-OER electrolyte. This illustrates that during OER process, severe S atoms were oxidized from NLOS-1. Apart from some adsorbed on the catalyst surface in the form of SO_4^{2-}, most of the leached S species were dissolved into the electrolyte. On the other hand, when the reaction of Ni_3S_2@CC was prolonged to 72 h, much more Ni atoms were lost in the electrolyte, indicating that the presence of La could stabilize the active Ni species and further promoted the catalytic durability.

Table S6 EXAFS fitting parameters at the La L_3-edge for pre- and post-OER NLOS-1.

Samples	Shell	CN	R(Å)	σ^2 (10^{-3} Å^2)	R factor
Pre-OER	La-O	4.5±0.3	2.38±0.02	10.7±1.2	0.009
	La-S	4.6±0.5	3.02±0.01	11.2±1.4	
Post-OER	La-O	9.8±0.8	2.5±0.02	8.7±1.1	0.016
	La-S	3.1±1.7	3.1±0.04	9.8±5.9	

In Table S6, CN, R, and σ^2 represent coordination number, distance between absorber and backscatter atoms, respectively. R factor reflects the goodness of the fitting.

The obtained EXAFS data were preprocessed using Athena [S38–S40]. Then Fourier transformed fitting was performed by using Artemis. The k-range of 2.6-9.5 Å^{-1} and R range of 1.7-3.0 Å were employed for the fitting. The model of pre- and post-OER NLOS-1 were used to obtain the simulated scattering paths.
